Decorators Functions That Make Functions

C-START Python PD Workshop

Functions are *first-class citizens* in Python:

```
>>> def identity(x):
... return x
...
>>> type(identity)
<class 'function'>
```

Functions are *first-class citizens* in Python:

```
>>> def identity(x):
... return x
```

```
...
>>> type(identity)
<class 'function'>
```

Functions can also be written anonymously as lambdas:

```
>>> identity = lambda x:x
>>> identity(42)
42
```

. . .

Functions are *first-class citizens* in Python:

```
>>> def identity(x):
```

... return x

```
>>> type(identity)
<class 'function'>
```

Functions can also be written anonymously as lambdas:

```
>>> identity = lambda x:x
>>> identity(42)
42
```

In this case, the first style is preferred. It's a bit easier to read, not to mention it's actually named.

Python allows you to define functions that take a variable number of positional (*args) or keyword (**kwargs) arguments. In principle, this really just works like tuple expansion/collection. Python allows you to define functions that take a variable number of positional (*args) or keyword (**kwargs) arguments. In principle, this really just works like tuple expansion/collection.

```
def crazyprinter(*args, **kwargs):
    for arg in args:
        print(arg)
    for k, v in kwargs.items():
        print("{}={}".format(k, v))
crazyprinter("hello", "cheese", bar="foo")
# hello
# cheese
# bar=foo
```

Oproperty as we just saw is what is called a decorator. Decorators are really just a pretty way to wrap functions using functions that return functions.

@property as we just saw is what is called a decorator. Decorators are really just a pretty way to wrap functions using functions that return functions.

Both the following are equivalent:

```
@logging
def foo(bar, baz):
    return bar + baz - 42
# equivalent to...
def foo(bar, baz):
    return bar + baz - 42
foo = logging(foo)
```

When defining wrapper functions, you should decorate it with wraps from functools, this will keep attributes about the function.

```
from functools import wraps
```

```
def logging(func):
    @wraps(func)
    def wrapper(*args, **kwargs):
        result = func(*args, **kwargs)
        print(result)
        return result
    return wrapper
```

lru_cache from functools can be a quick way to make a recursive function with a recurrence relation fast. Here's an example: lru_cache from functools can be a quick way to make a recursive function with a recurrence relation fast. Here's an example:

from functools import lru_cache

```
@lru_cache(maxsize=None)
def fibonacci(n):
    if n == 0 or n == 1:
        return n
    return fibonacci(n - 1) + fibonacci(n - 2)
```

Welford's Equations are a one-pass mean and standard deviation algorithm. One important property is that we won't have to store the results in a list. Welford's Equations are a one-pass mean and standard deviation algorithm. One important property is that we won't have to store the results in a list.

Our goal will be to implement a decorator we can use like this:

```
@Welford
def diceroll(u):
    return int(u * 6) + 1
```

call diceroll with some u's in (0, 1)

print(diceroll.mean, diceroll.stdev)

Decorators in the Wild: Implementing Welford

The key here is that we can make callable objects using __call__.

```
from functools import update_wrapper
from math import sqrt
class Welford:
    def init (self, f):
        self.f = f
       update_wrapper(self, f)
       self.mean = 0
       self.v = 0
       self.trials = 0
    def call (self, *args, **kwargs);
        r = self.f(*args, **kwargs)
       self trials += 1
       d = r - self.mean
        self.v += d**2 * (self.trials - 1)/self.trials
        self.mean += d/self.trials
        return r
    Oproperty
    def stdev(self):
        return sqrt(self.v/self.trials) if self.trials else 0
```

 Decorators can wrap classes as well as functions. A practical example might be creating a decorator which adds attributes of a class to a database (a @model decorator?)

- Decorators can wrap classes as well as functions. A practical example might be creating a decorator which adds attributes of a class to a database (a @model decorator?)
- When multiple decorators are typed, they are applied bottom-up.
